EXAMINER

HUISMAN, DAVID J

ART UNIT	PAPER NUMBER
----------	--------------

2183

DATE MAILED: 09/21/2004

Please find below and/or attached an Office communication concerning this application or proceeding.

Office Action Summary

Application No.

09/748,785

Applicant(s)

COFLER ET AL

Examiner

David J. Huisman

Art Unit

2183

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
 - If the period for reply specified above is less than thirty (30) days, a reply within the statutory minimum of thirty (30) days will be considered timely.
 - If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
 - Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133).
- Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

- 1) ☒ Responsive to communication(s) filed on 30 June 2004.
- 2a) ☒ This action is **FINAL**. 2b) ☐ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

- 4) ☒ Claim(s) 1-15 is/are pending in the application.
- 4a) Of the above claim(s) _____ is/are withdrawn from consideration.
- 5) ☐ Claim(s) _____ is/are allowed.
- 6) ☒ Claim(s) 1-15 is/are rejected.
- 7) ☐ Claim(s) _____ is/are objected to.
- 8) ☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☒ The drawing(s) filed on 30 June 2004 is/are: a) ☒ accepted or b) ☐ objected to by the Examiner.
- Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).
- Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

- 12) ☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☒ All b) ☐ Some * c) ☐ None of:
1. ☒ Certified copies of the priority documents have been received.
2. ☐ Certified copies of the priority documents have been received in Application No. _____.
3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

Attachment(s)

- 1) ☒ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-948)
- 3) ☒ Information Disclosure Statement(s) (PTO-1449 or PTO/SB/08)
Paper No(s)/Mail Date 30 June 2004.
- 4) ☐ Interview Summary (PTO-413)
Paper No(s)/Mail Date. _____.
- 5) ☐ Notice of Informal Patent Application (PTO-152)
- 6) ☐ Other: _____.

DETAILED ACTION

1. Claims 1-15 have been examined.

Papers Submitted

2. It is hereby acknowledged that the following papers have been received and placed of record in the file: Extension of Time, Amendment, and IDS as received on 6/30/2004.

Claim Rejections - 35 USC § 103

3. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

4. Claims 1-5 and 8-10 are rejected under 35 U.S.C. 103(a) as being unpatentable over Song, U.S. Patent No. 5,546,599 (as applied in the previous Office Action), in view of Grochowski et al., U.S. Patent No. 6,353,883 (as applied in the previous Office Action and herein referred to as Grochowski), and further in view of Hennessy and Patterson, Computer Architecture - A Quantitative Approach, 2nd Edition, 1996 (as applied in the previous Office Action and herein referred to as Hennessy). In addition, Hennessy, page 180, and The Free On-Line Dictionary of Computing (1995), are cited as extrinsic evidence for respectively showing that exceptions and breakpoints are synonymous and for showing the definition of "page fault," which is a specific type of exception.

Art Unit: 2183

5. Referring to claim 1, Song has taught a computer system for executing instructions comprising:

a) a fetch unit for fetching instructions to be executed. See Fig.3, and note that instructions are fetched from instruction cache 14 into instruction buffer 70.

b) a decode unit for decoding said instructions. See Fig.3, component 72.

c) at least one pipelined execution unit for executing decoded instructions. From Fig.3, it should be realized that decoded instructions are eventually dispatched to execution units (which are shown in Fig.1). In addition, see column 4, lines 11-16, and note that that the execution units exist within a multi-stage pipeline and that the execution units may require multiple cycles themselves (specifically, in Fig. 13 and 15).

d) an emulation unit including control circuitry which cooperates with the decode unit to selectively control the decode unit to implement a precise watch or a non-precise watch on detection of a breakpoint wherein according to a non-precise watch, the instruction causing the breakpoint and subsequent instructions are permitted to be supplied from the decode unit to the at least one execution unit. Note from the abstract, column 22, lines 30-34, and claim 1 (of Song), that the system is able to operate in precise exception mode. In this mode, the instruction causing the exception/breakpoint (see Hennessy page 180 and note that a breakpoint is an exception) is prevented from being executed. Furthermore, note from column 22, lines 16-29, that the system also operates in a non-precise (imprecise) exception mode. More specifically, the instruction causing the exception (breakpoint) along with subsequent instructions are allowed to proceed through the pipeline so that increased performance is achieved. Song has not explicitly taught that according to a precise watch mode, the instruction causing the breakpoint is not

Art Unit: 2183

decoded. However, Hennessy has taught that exceptions (breakpoints) may occur when an instruction is to be fetched. See Figure 3.41 on page 184. A person would have realized that if a page fault exception occurs during the fetch, then the fetch has failed and the instruction that is supposed to be fetched will not be decoded. A page fault, according to FOLDOC (see attached definition) is "... an access to a page of memory that is not currently mapped to physical memory. When a page fault occurs, the operating system either fetches the page in from secondary storage (usually disk)...". That is, if an instruction is to be fetched but a page fault occurs, then that instruction is not currently in memory, and consequently it cannot be fetched and decoded until after the operating system fetches the page from secondary storage (the OS fixes the exception). As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to not decode an instruction during precise watch mode.

e) Song has not taught that:

- the executed instructions are predicated instructions, wherein each instruction includes a guard, the value of which determines whether or not that instruction is executed. However, Grochowski has taught the concept of executing predicated instruction having guards. See Fig.6, step 610, and Fig.1 (note that p2 is a predicate/guard).
- the execution unit is associated with a guard register file holding values of the guards to allow resolution of the guards to be made. However, Grochowski has taught such a concept. See Fig.3A, component 300, and column 2, lines 65-67. Note that the predicate table (register file), is updated with actual predicate values, which are in turn used as predictions for speculatively executed instructions.

Art Unit: 2183

- instructions are supplied to the execution unit while guard resolution in said execution pipeline is awaited. However, Grochowski has taught such a concept. See column 3, lines 4-35. More specifically, predicated instructions are allowed to progress through the pipeline before its corresponding guard is resolved.

A person of ordinary skill in the art would have recognized that by implementing predicated instructions with predicate prediction within Song, a) conditional branches could be eliminated, thereby reducing the amount of instructions required in the instruction set, and b) predicated instructions would be speculatively executed (i.e., executed before the corresponding guard is resolved), thereby maximizing throughput by executing predicated instructions as soon as possible. As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to modify Song to include predicated instructions and predicate prediction, as taught by Grochowski.

6. Referring to claim 2, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song has further taught that the system is implemented on a single chip. See Fig.1, component 10, and column 2, lines 47-48.

7. Referring to claim 3, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song has further taught a program memory for holding said instructions to be executed. See Fig.1 and column 2, lines 60-61.

8. Referring to claim 4, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song has not explicitly taught that the emulation unit is associated with an emulation program memory which holds debug code which is executed in a debug mode. However, recall that Song has taught handling exceptions (see

Art Unit: 2183

Fig.3 and column 8, lines 10-13). As is known in the art, when an exception/interrupt is triggered during execution of a program, a handling routine must be invoked in order to correct the error associated with the exception/interrupt before execution of the main program may resume. According to "The American Heritage® Dictionary of the English Language, 3rd Edition, 1992," the word "debug" is defined as "to search for and eliminate malfunctioning elements or errors in." Consequently, when an error occurs in an executing program in Song, an exception will be triggered. A handling routine (debug code) is invoked in order to search for the problem causing the exception and eliminate the error. This process would be considered debug mode. In addition, it should be realized that the debug code must be stored somewhere (emulation program memory). As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to implement an emulation program memory which holds debug code which is executed in a debug mode in Song since this feature is well known, accepted, and expected in the art of exceptions and exception handling.

9. Referring to claim 5, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song in view of Grochowski has further taught that when the emulation unit is in a precise watch mode, it is operable to issue a request to the execution pipeline for guard resolution, the guard resolution being transmitted to the control circuitry of the emulation unit which is responsive thereto to control operation of the decode unit. Note from column 3, lines 25-35, of Grochowski, that a predicated instruction is prevented from executing until the guard is resolved. This is advantageous in that a time-expensive recovery is not required if the guard is improperly predicted. Therefore, when Song is in precise watch mode, Grochowski has taught that it is beneficial to issue a request to the execution pipeline for

Art Unit: 2183

guard resolution for the aforementioned reasons. As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to issue a request to the execution pipeline for guard resolution during precise watch mode in Song.

10. Referring to claim 8, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song has further taught a microinstruction generator which receives instructions from the decode unit and supplies microinstructions to the execution pipeline. See Fig.3, component 74, and column 7, lines 23-26, and note that up to 4 microinstructions that are to be dispatched are determined (aka produced or generated). In addition, Grochowski has taught that said microinstructions include fields for holding respective guards to be resolved. For instance, see column 5, lines 36-41, and note that the predicate is extracted from the instruction. Therefore, there must be a field within the instruction which specifies the predicate.

11. Referring to claim 9, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song has further taught a plurality of parallel pipelined execution units, including at least two data unit pipelines for executing data processing instructions and at least two address unit pipelines for executing memory access instructions. From Fig.1, it should be seen that floating-point unit (30) and fixed point unit A (22) are data units in that they will execute floating and fixed point instructions (such as add, subtract, mult, etc.), and load/store unit (28) and complex fixed-point unit are address units in that the load/store unit will execute loads and stores, which access memory, and complex fixed point unit also accesses memory (general and special purpose registers, which are forms of memory). Finally, it should be realized that to make separable is not a generally a patentable feature or would be an

Art Unit: 2183

obvious improvement. More specifically, it would have been obvious to one of ordinary skill in the art at the time of the invention to modify Song's load/store unit into a separate load unit and store unit, thereby yielding two address units.

12. Referring to claim 10, Song has taught a method of debugging an on-chip processor which is arranged to execute instructions, the method comprising:

a) fetching instructions to be executed. See Fig.3, and note that instructions are fetched from instruction cache 14 into instruction buffer 70.

b) decoding said instructions. See Fig.3, component 72.

c) executing decoded instructions, said executing step including resolving values of the guards of the instructions. From Fig.3, it should be realized that decoded instructions are eventually dispatched to execution units (which are shown in Fig.1).

d) and detecting instructions which have a debug effect and acting on said instructions in dependence on whether the processor is in a precise watch mode or a non-precise watch mode wherein, according to a non-precise watch mode, the instruction and subsequent instruction are supplied and executed normally. Note from the abstract, column 22, lines 30-34, and claim 1 (of Song), that the system is able to operate in precise exception mode. In this mode, the instruction causing the exception (breakpoint) is prevented from being executed (i.e., held at decode stage). Furthermore, note from column 22, lines 16-29, that the system also operates in a non-precise (imprecise) exception mode. More specifically, the instruction causing the exception (breakpoint) along with subsequent instructions are allowed to proceed through the pipeline so that increased performance is achieved. Song has not explicitly taught that according to a precise watch mode, the instruction is not decoded. However, Hennessy has taught that exceptions

Art Unit: 2183

(breakpoints) may occur when an instruction is to be fetched. See Figure 3.41 on page 184. A person would have realized that if a page fault exception occurs during the fetch, then the fetch has failed and the instruction that is supposed to be fetched will not be decoded. A page fault, according to FOLDOC (see attached definition) is "...an access to a page of memory that is not currently mapped to physical memory. When a page fault occurs, the operating system either fetches the page in from secondary storage (usually disk)...". That is, if an instruction is to be fetched but a page fault occurs, then that instruction is not currently in memory, and consequently it cannot be fetched and decoded until after the operating system fetches the page from secondary storage (the OS fixes the exception). As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to not decode an instruction during precise watch mode.

e) Song has also not taught that:

- the executed instructions are predicated instructions, wherein each instruction includes a guard, the value of which determines whether or not that instruction is executed. However, Grochowski has taught the concept of executing predicated instruction having guards. See Fig.6, step 610, and Fig.1 (note that p2 is a predicate/guard).
- Said executing step includes resolving values of the guards of the instructions. However, Grochowski has taught such a concept. See Fig.1. Note that by executing the COMPARE instruction, the guard p2 will be resolved.
- instructions are supplied to the execution unit while guard resolution in said execution pipeline is awaited. However, Grochowski has taught such a concept.

See column 3, lines 4-35. More specifically, predicated instructions are allowed to progress through the pipeline before its corresponding guard is resolved.

A person of ordinary skill in the art would have recognized that by implementing predicated instructions with predicate prediction within Song, a) conditional branches could be eliminated, thereby reducing the amount of instructions required in the instruction set, and b) predicated instructions would be speculatively executed (i.e., executed before the corresponding guard is resolved), thereby maximizing throughput by executing predicated instructions as soon as possible. As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to modify Song to include predicated instructions and predicate prediction, as taught by Grochowski.

It should be further realized that according to "The American Heritage® Dictionary of the English Language, 3rd Edition, 1992," the word "debug" is defined as "to search for and eliminate malfunctioning elements or errors in." Consequently, when an error occurs in an executing program in Song, an exception will be triggered. A handling routine (debug code) is invoked in order to search for the problem causing the exception and eliminate the error. This process would be considered debugging.

13. Claims 6 and 13 are rejected under 35 U.S.C. 103(a) as being unpatentable over Song in view of Grochowski and further in view of Hennessy, as applied above, and further in view of Matt et al., EP 0943995A2 (as disclosed by applicant, applied in the previous Office Action, and herein referred to as Matt).

Art Unit: 2183

14. Referring to claim 6, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 5. Song in view of Grochowski and further in view of Hennessy has not taught the specifics set forth in claim 6. However, Matt has taught issuing a go command and divert command to the decode unit responsive to receipt of the guard resolution from the execution pipeline, wherein a go command allows the instruction which caused the breakpoint and subsequent instructions to be normally decoded and executed, and a divert command sets the computer system into a debug mode. See column 4, lines 6-40. More specifically, when a break event occurs, (which would include exceptions taught by Song), the system would issue either a command to resume execution (go command) or a command to execute a service routine (divert command). This allows for real-time execution control for debug functions within a processor, as taught by Matt in column 4, lines 6-9. As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to modify Song in view of Grochowski and further in view of Hennessy in view of Matt such that an go and divert commands may be issued in order to allow for real-time execution control for debug functions.

15. Referring to claim 13, Song in view of Grochowski in view of Hennessy has taught a method as described in claim 10.

a) Furthermore, Song in view of Grochowski has taught that in a precise watch mode, a request for guard resolution is issued such that an instruction guard is resolved prior to execution of the instruction. Note from column 3, lines 25-35, of Grochowski, that a predicated instruction is prevented from executing until the guard is resolved. This is advantageous in that a time-expensive recovery is not required if the guard is improperly predicted. Therefore, when Song is

Art Unit: 2183

in precise watch mode, Grochowski has taught that it is beneficial to issue a request to the execution pipeline for guard resolution for the aforementioned reasons. As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to issue a request to the execution pipeline for guard resolution during precise watch mode in Song.

b) Song in view of Grochowski in view of Hennessy has not taught selectively causing issue of one of a go command and a debug command responsive to the guard resolution. However, Matt has taught issuing a go command and divert command to the decode unit responsive to receipt of the guard resolution from the execution pipeline, wherein a go command allows the instruction which caused the breakpoint and subsequent instructions to be normally decoded and executed, and a divert command sets the computer system into a debug mode. See column 4, lines 6-40. More specifically, when a break event occurs, (which would include exceptions taught by Song), the system would issue either a command to resume execution (go command) or a command to execute a service routine (divert command). This allows for real-time execution control for debug functions within a processor, as taught by Matt in column 4, lines 6-9. As a result, it would have been obvious to one of ordinary skill in the art at the time of the invention to modify Song in view of Grochowski in view of Matt such that an go and divert commands may be issued in order to allow for real-time execution control for debug functions.

16. Claims 7 and 15 are rejected under 35 U.S.C. 103(a) as being unpatentable over Song in view of Grochowski and further in view of Hennessy, as applied above, and further in view of Adler et al., U.S. Patent No. 5,627,981 (herein referred to as Adler).

Art Unit: 2183

17. Referring to claim 7, Song in view of Grochowski and further in view of Hennessy has taught a computer system as described in claim 1. Song in view of Grochowski and further in view of Hennessy has not taught the specifics set forth in claim 7. However, Adler has taught a system in which the instruction which caused the breakpoint (exception) and subsequent instructions are decoded and executed normally until such time as said instruction reaches the execution pipeline where its guard is resolved such that a commit signal is generated to the control circuitry of the emulation unit, and wherein the emulation unit is responsive to receipt of the commit signal to set the computer system into a debug mode. See the last 8 lines of the abstract and Fig.9. In essence, predicated instructions are executed speculatively (i.e., executed normally without knowing the actual value of the guard/predicate). When the instruction is at a commit point, and if the instruction's predicate is true, then if that instruction caused a breakpoint (or exception), then it will be serviced (debug mode). This scheme allows errors that should not have occurred (errors resulting from instructions that should not have executed) to be ignored while servicing the errors that should have occurred (errors resulting from instructions that have properly executed. See column 3, lines 20-42. As a result, it would have been obvious to one of ordinary skill in the art to modify the system taught by Song in view of Grochowski and further in view of Hennessy such that it includes the functionality of Adler.

18. Referring to claim 15, Song in view of Grochowski has taught a method as described in claim 10. Song in view of Grochowski in view of Hennessy has not taught the specifics set forth in claim 15. However, Adler has taught a system in which the instruction which caused the breakpoint (exception) and subsequent instructions are decoded and executed normally until such time as the guard is resolved wherein, if the guard is resolved such that a position commit signal

Art Unit: 2183

is generated, the processor is set into a debug mode. See the last 8 lines of the abstract and Fig. 9. In essence, predicated instructions are executed speculatively (i.e., executed normally without knowing the actual value of the guard/predicate). When the instruction is at a commit point, and if the instruction's predicate is true, then if that instruction caused a breakpoint (or exception), then it will be serviced (debug mode). This scheme allows errors that should not have occurred (errors resulting from instructions that should not have executed) to be ignored while servicing the errors that should have occurred (errors resulting from instructions that have properly executed. See column 3, lines 20-42. As a result, it would have been obvious to one of ordinary skill in the art to modify the system taught by Song in view of Grochowski such that it includes the functionality of Adler.

19. Claim 11 is rejected under 35 U.S.C. 103(a) as being unpatentable over Song in view of Grochowski in view Hennessy, as applied above, and further in view of Kurakazu, U.S. Patent No. 5,644,703 (as disclosed by applicant, applied in the previous Office Action, and herein referred to as Kurakazu).

20. Referring to claim 11, Song in view of Grochowski in view Hennessy has taught a method as described in claim 10. Song in view of Grochowski in view Hennessy has not explicitly taught that breakpoints are detected at instructions having certain program counts. However, Kurakazu has taught that an address break is well known, accepted, and expected in the art. See column 1, lines 12-20. More specifically, a user is allowed to set a breakpoint at a specified address in order to determine the status of the system at that particular point regardless of the instruction that is at the address. As a result, it would have been obvious to one of

Art Unit: 2183

ordinary skill in the art at the time of the invention to modify Song in view of Grochowski in view of Hennessy such that breakpoints are detected at instructions having certain program counts (addresses).

21. Claims 12 and 14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Song in view of Grochowski in view Hennessy, as applied above, and further in view of Christensen et al., U.S. Patent No. 5,752,013 (as disclosed by applicant, applied in the previous Office Action, and herein referred to as Christensen).

22. Referring to claim 12, Song in view of Grochowski in view Hennessy has taught a method as described in claim 10. Song in view of Grochowski in view Hennessy has not taught that breakpoints are detected at instructions having certain opcodes. However, Christensen has taught such a concept. See column 1, lines 64-67. Note that particular instructions may be used as breakpoints. For instance, maybe the program will break at branch-type instructions (which have branch opcodes). Since Christensen has taught that this type of break is common in the art, it would have been obvious to one of ordinary skill in the art at the time of the invention to implement such a feature in Song in view of Grochowski in view of Hennessy.

23. Referring to claim 14, Song in view of Grochowski in view Hennessy in view of Christensen has taught a method as described in claim 12. Furthermore, recall that Song has taught handling exceptions (see Fig.3 and column 8, lines 10-13). As is known in the art, when an exception/interrupt is triggered during execution of a program, a handling routine must be invoked in order to correct the error associated with the exception/interrupt before execution of the main program may resume. According to "The American Heritage® Dictionary of the

Art Unit: 2183

English Language, 3rd Edition, 1992,” the word “debug” is defined as “to search for and eliminate malfunctioning elements or errors in.” Consequently, when an error occurs in an executing program in Song, an exception will be triggered. A handling routine (debug code) is invoked and executed by the processor in order to search for the problem causing the exception and eliminate the error. This process would be considered a debug mode.

Response to Arguments

24. Applicant's arguments filed on June 30, 2004, have been fully considered but they are not persuasive.

25. Applicant argues the novelty/rejection of claims 1 and 10 on page 16 of the remarks, in substance that:

“Indeed, Song teaches away from the idea of not decoding an instruction if an exception occurs in the fetch stage. Specifically, Song discloses that for instruction fetch and decode related exceptions (IFDRE), the processor detects such exceptions at the fetch or decode stage and in response dispatches the instruction that causes such an exception to a reservation station of an execution unit. See Song, Col. 9, lines 47-64.”

26. These arguments are not found persuasive for the following reasons:

a) The examiner conceded that Song has not taught not decoding an instruction causing a breakpoint in precise mode, but the examiner asserts that applicant is reading the claim too narrowly. The claim language in question is the following: “...according to a precise watch mode, the instruction causing the breakpoint is not decoded.” As mentioned, Hennessy has taught that exceptions may occur when an instruction is to be fetched. See Figure 3.41 on page 184. A person would have realized that if a page fault exception occurs during the fetch, then the fetch has failed and the instruction that is supposed to be fetched will not be decoded **until after the exception is fixed**. More specifically, a page fault, according to FOLDOP (see attached

definition) is defined as "...an access to a page of memory that is not currently mapped to physical memory. When a page fault occurs, the operating system either fetches the page in from secondary storage (usually disk)..." That is, if an instruction is to be fetched but a page fault occurs, then that instruction is not currently in memory, and consequently it cannot be decoded until after the operating system fetches the page from secondary storage (the OS fixes the exception). Once the page is fetched, then the instruction will be fetched and decoded but the decoding occurs after the exception is processed.

Applicant's use of the word "comprising" in the claims does not exclude unrecited steps. More specifically, the transitional term "comprising", which is synonymous with "including," "containing," or "characterized by," is inclusive or open-ended and does not exclude additional, unrecited elements or method steps. See, e.g., > *Invitrogen Corp. v. Biocrest Mfg., L.P.*, 327 F.3d 1364, 1368, 66 USPQ2d 1631, 1634 (Fed. Cir. 2003) ("The transition comprising' in a method claim indicates that the claim is open-ended and allows for additional steps."); *Genentech, Inc. v. Chiron Corp.*, 112 F.3d 495, 501, 42 USPQ2d 1608, 1613 (Fed. Cir. 1997) ("Comprising" is a term of art used in claim language which means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim.); *Moleculon Research Corp. v. CBS, Inc.*, 793 F.2d 1261, 229 USPQ 805 (Fed. Cir. 1986); *In re Baxter*, 656 F.2d 679, 686, 210 USPQ 795, 803 (CCPA 1981); *Ex parte Davis*, 80 USPQ 448, 450 (Bd. App. 1948) ("comprising" leaves "the claim open for the inclusion of unspecified ingredients even in major amounts"). Therefore, the examiner asserts that Song in view of Hennessy has taught "...according to a precise watch mode, the instruction causing the breakpoint is not decoded **until after the exception is fixed.**"

Applicant is arguing that the instruction which causes a breakpoint (in precise mode) will **never** be decoded. However, applicant is only claiming that the instruction is **not** decoded. Had applicant used the claim language "...according to a precise watch mode, the instruction causing the breakpoint is never decoded," the prior art of record would have been overcome.

27. Applicant argues the novelty/rejection of claims 1 and 10 on page 16 of the remarks, in substance that:

"The imprecise floating point exception mode and the precise floating exception mode are different from the precise watch and non-precise watch recited in claim 1. First, the precise watch and imprecise watch recited in claim 1 are implemented on detection of a breakpoint, not detection of a floating point exception. A breakpoint is different from a floating point exception."

28. These arguments are not found persuasive for the following reasons:

a) In general, an exception is a break in normal program execution in order to fix an error or malfunction. In this broad sense, an exception is a break point, i.e., a point of breaking of normal execution for error correction. In addition, Hennessy, on page 180, has shown that a breakpoint is an exception.

29. Applicant argues the novelty/rejection of claims 1 and 10 on page 18 of the remarks, in substance that:

"Further, Song does not teach or suggest circuitry that "cooperates with the decode unit to selectively control the decode unit to implement a precise watch or a non-precise watch." Indeed, in the floating-point exception modes of Song, the instructions have already passed through the decode stage, as a floating point exception is not detected until the instruction is executed. Thus, the precise and imprecise floating point exception mode disclosed by Song does not cooperate in any with the decode unit."

30. These arguments are not found persuasive for the following reasons:

Art Unit: 2183

a) As described above, in a precise mode, it would have been obvious for an instruction causing a breakpoint to not be decoded. And, in an imprecise mode, instructions may be passed along. Therefore, the circuitry will cooperate with the decoder in each of the modes that that the decoder operates appropriately.

Conclusion

31. Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP § 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire **THREE MONTHS** from the mailing date of this action. In the event a first reply is filed within **TWO MONTHS** of the mailing date of this final action and the advisory action is not mailed until after the end of the **THREE-MONTH** shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than **SIX MONTHS** from the date of this final action.

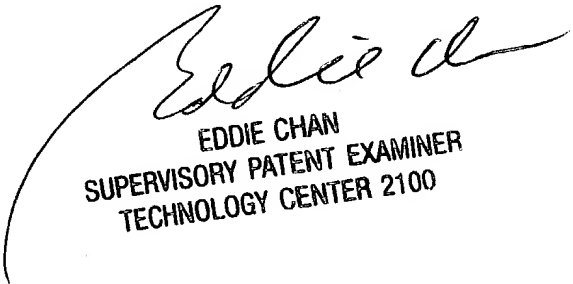

Any inquiry concerning this communication or earlier communications from the examiner should be directed to David J. Huisman whose telephone number is (703) 305-7811. The examiner can normally be reached on Monday-Friday (8:00-4:30).

Art Unit: 2183

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Eddie Chan can be reached on (703) 305-9712. The fax phone number for the organization where this application or proceeding is assigned is 703-872-9306.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free).
